Ownership Structure and Economic Growth: A Network Approach

Koki Okumura

UCLA

Ownership Structure $\Longrightarrow$ Economic Growth?

- US: BlackRock, Vanguard, and State Street control a quarter of votes of S&P 500 firms
- Korea: In the mid-1990s, the top five chaebols accounted for 10% of the GDP (Chang, 2003)
- Japan: In the early 1900s, the top three zaibatsu held 30% of total assets within the top 100 manufacturing firms (Takeda, 2020)

Ownership Structure $\Longrightarrow$ Economic Growth?

- US: BlackRock, Vanguard, and State Street control a quarter of votes of S&P 500 firms
- Korea: In the mid-1990s, the top five chaebols accounted for 10% of the GDP (Chang, 2003)
- Japan: In the early 1900s, the top three zaibatsu held 30% of total assets within the top 100 manufacturing firms (Takeda, 2020)
- Ownership structure (common ownership / cross ownership / M&A) $\rightarrow$ economic growth?
  - Business stealing
  - Technology spillovers

Framework: Growth + IO (Hopenhayn and Okumura, 2024) + Ownership

- Quantitative model of endogenous growth, competition, and ownership structure
- Dynamic R&D involving many oligopolists
  - Existing models: a few firms in each industry (mostly monopoly or duopoly)
  - Public patenting firms in the US ($\simeq$ 1000 firms)
  - Match to data at firm (pair) level
- Quantify Three Networks
  - Ownership structure
  - Product market rivalry
  - Technology spillovers

Quantify the Impact of Common Ownership and Policy

- Ownership concentration in production:
  - Appropriability of returns from innovation $\uparrow \Longrightarrow g \uparrow$
  - Dispersed ownership $\Longrightarrow$ Observed common ownership: $g \uparrow$ by 0.027% in 2017
- Ownership concentration in R&D:
  - Internalization of business stealing $\Longrightarrow g \downarrow$
  - Internalization of technology spillover $\Longrightarrow g \uparrow$
  - Dispersed ownership $\Longrightarrow$ Observed common ownership: $g \downarrow$ by 0.084% in 2017
- Uniform R&D subsidy
  - Optimal rate in 2017 is $s = 32\%$, which increases g by 0.25%
  - CE welfare loss relative to optimal R&D allocation: 0.7% ($s = 0\%$) $\Longrightarrow$ 0.1% ($s = 30\%$)

Literature

- Competition & innovation:

  d'Aspremont and Jacquemin (1988); Aghion et al. (2001, 2005); Acemoglu and Akcigit (2012); Aghion et al. (2013); Bloom et al. (2013); Lopez and Vives (2019); Peters (2020); Akcigit and Ates (2021, 2023); Liu et al. (2022); Cavenaile et al. (2023); Anton et al. (2023, 2024); Kini et al. (2024)

  Quantitative endogenous growth model matched to firm-(pair-)level data

- Hedonic demand / empirical IO:

  Lancaster (1966); Rosen (1974); Epple (1987); Berry et al. (1995); Nevo (2001); Pellegrino (2024); Ederer and Pellegrino (2024)

  Dynamic general equilibrium

- Oligopoly / Common ownership / market power:

  Rubinstein and Yaari (1983); Rotemberg (1984); Neary (2003); Atkeson and Burstein (2008); Gutierrez and Philippon (2017); He and Huang (2017); Azar et al. (2018, 2022); Autor et al. (2020); Baqaee and Farhi (2020); De Loecker et al. (2020); Azar and Vives (2021); Edmond et al. (2023)

Overview of Framework and Estimation

- Firms compete to maximize shareholders' returns $\Longrightarrow$
  - Firms partially consider the profits of other firms owned by the same shareholders
- Overlapping ownership among firms that are close in ...
  - product space $\Longrightarrow$ internalize business stealing effect $\Longrightarrow$ R&D $\downarrow$
  - technology space $\Longrightarrow$ internalize technology spillover $\Longrightarrow$ R&D $\uparrow$

Overview of Framework and Estimation

- Firms compete to maximize shareholders' returns $\Longrightarrow$
  - Firms partially consider the profits of other firms owned by the same shareholders
- Overlapping ownership among firms that are close in ...
  - product space $\Longrightarrow$ internalize business stealing effect $\Longrightarrow$ R&D $\downarrow$
  - technology space $\Longrightarrow$ internalize technology spillover $\Longrightarrow$ R&D $\uparrow$

Networks	Measurement
Ownership structure	Investor holdings in 13f filings (Backus et al., 2021)
Product market rivalry	Product proximity (Hoberg and Phillips, 2016): Text analysis of product description in 10k filings
Technology spillover	Technology proximity (Bloom et al., 2013): Patent classification

Generalized Hedonic-Linear Demand (Pellegrino, 2024)

- $i \in \{1, 2, \ldots, n\}$: firms / products
- 1 unit of product i provides
  - 1 unit of idiosyncratic characteristic $i \in \{1, 2, \ldots, n\}$
  - $\psi_{k,i}$ unit of common characteristic $k \in \{n+1, n+2, \ldots, n+n_k\}$ where $\sum_k \psi_{k,i}^2 = 1$

Generalized Hedonic-Linear Demand (Pellegrino, 2024)

- $i \in \{1, 2, \ldots, n\}$: firms / products
- 1 unit of product i provides
  - 1 unit of idiosyncratic characteristic $i \in \{1, 2, \ldots, n\}$
  - $\psi_{k,i}$ unit of common characteristic $k \in \{n+1, n+2, \ldots, n+n_k\}$ where $\sum_k \psi_{k,i}^2 = 1$
- Aggregate each characteristic:

$$y_{k,t} = \begin{cases} q_{k,t} & k = 1, 2, \ldots, n \\ \sum_i \psi_{k,i} q_{i,t} & k = n+1, n+2, \ldots, n+n_k \end{cases}$$

- Linear quadratic aggregator over characteristics:

$$Y_t = (1-\alpha) \sum_{k=1}^{n} \left(\underbrace{\hat{b}_{k,t} y_{k,t} - \frac{1}{2} y_{k,t}^2}_{\text{idiosyncratic characteristic}} \right) + \alpha \sum_{k=n+1}^{n+n_k} \left(\underbrace{\hat{b}_{k,t} y_{k,t} - \frac{1}{2} y_{k,t}^2}_{\text{common characteristic}} \right)$$

Substitutability $\propto$ Cosine Similarity (Pellegrino, 2024)

- $Y_t = \mathbf{q}_t^T \underbrace{\mathbf{b}_t}_{\text{quality}} - \frac{1}{2}\mathbf{q}_t^T \Sigma \mathbf{q}_t$ where $\underbrace{\sigma_{ij}}_{\text{substitutabiliy}} = \alpha \underbrace{\sum_k \psi_{k,i}\psi_{k,j}}_{\text{cosine similarity}} \; (i \neq j)$ and $\underbrace{\sigma_{ii}}_{\text{diagonal}} = 1$ elasticity

Substitutability ∝ Cosine Similarity (Pellegrino, 2024)

- $Y_t = \mathbf{q}_t^T \underbrace{\mathbf{b}_t}_{\text{quality}} - \frac{1}{2}\mathbf{q}_t^T \Sigma \mathbf{q}_t$ where $\underbrace{\sigma_{ij}}_{\text{substitutabiliy}} = \alpha \underbrace{\sum_k \psi_{k,i}\psi_{k,j}}_{\text{cosine similarity}} \; (i \neq j)$ and $\underbrace{\sigma_{ii}}_{\text{diagonal}} = 1$ elasticity

Technology

- Production technology: $q_{i,t} = a_{i,t} l_{i,t}$
- Firms allocate their knowledge capital to improve product quality and labor productivity:

$$\underbrace{\zeta a_{i,t}}_{\text{productivity}} + \underbrace{b_{i,t}}_{\text{quality}} = \underbrace{z_{i,t}}_{\text{knowledge capital}}$$

- Knowledge capital follows geometric Brownian motion:

$$d\mathbf{z}_t = \left(\underbrace{\Omega \mathbf{z}_t}_{\text{technology spillover}} + \underbrace{\mu \mathbf{x}_t}_{\text{R\&D}} \right) dt + \underbrace{\gamma \mathbf{z}_t dW_t}_{\text{shocks}}$$

  - $\Omega = [\omega_{ij}]$: technology spillover matrix
  - μ, γ: positive scalars

Market Clearing and Preference

- Inelastic labor supply:

$$L = \sum_i l_{i,t}$$

- Final good market clearing:

$$C_t + \underbrace{\sum_i x_{i,t}^2}_{\text{R\&D input}} = Y_t$$

  - Innovation elasticity is 0.5

- Risk neutral representative household:

$$\int_0^\infty \exp\left(-\rho t\right) C_t dt$$

Common Ownership Weights

- $z \in \{1, 2, \ldots, n_z\}$: funds
- s_{iz}: the proportion of shares in firm i owned by fund z where $\sum_z s_{iz} = 1$
- $\hat{V}_{i,t}$: value of firm i
- $\widetilde{V}_{z,t} \equiv \sum_i s_{iz} \hat{V}_{i,t}$: value of fund z

Common Ownership Weights

- $z \in \{1, 2, \ldots, n_z\}$: funds
- s_{iz}: the proportion of shares in firm i owned by fund z where $\sum_z s_{iz} = 1$
- $\hat{V}_{i,t}$: value of firm i
- $\widetilde{V}_{z,t} \equiv \sum_i s_{iz} \hat{V}_{i,t}$: value of fund z
- Firms' objective:

$$\sum_z s_{iz} \widetilde{V}_{z,t} \propto \sum_j \kappa_{ij} \hat{V}_{j,t} \quad \text{where} \quad \kappa_{ij} \equiv \frac{\mathbf{s}_i^T \mathbf{s}_j}{\mathbf{s}_i^T \mathbf{s}_i}$$

  - $\mathbf{s}_i \equiv [s_{i1}, \ldots, s_{iz}, \ldots, s_{in_z}]^T$: firm i's ownership structure
- $K = [\kappa_{ij}]$: common ownership weights (Rotemberg, 1984; Ederer and Pellegrino, 2024)
  - All diagonal elements are 1
  - All off-diagonal elements are 0 $\iff$ firm profit maximization
  - All elements are 1 $\iff$ monopoly

Cournot Competition

- Firm i's real gross profit:

$$\begin{aligned}\pi_{i,t} &= \frac{p_{i,t}}{P_t} q_{i,t} - \frac{w_t}{P_t} l_{i,t} \\ &= \left(b_{i,t} - \frac{1}{a_{i,t}} \frac{w_t}{P_t} - \sum_j \sigma_{ij} q_{j,t} \right) q_{i,t} \quad \text{where} \quad \zeta a_{i,t} + b_{i,t} = z_{i,t}\end{aligned}$$

- Given w_t/P_t, $z_{i,t}$, and $\{q_{j,t}\}_{j \neq i}$, firm i chooses $a_{i,t}$, $b_{i,t}$, and $q_{i,t}$ to maximize $\sum_j \kappa_{ij} \pi_{j,t}$

Cournot-Nash Equilibrium

- Firms choose labor productivity and product quality: $\zeta a_{i,t} = \sqrt{\zeta \frac{w_t}{P_t}}$, $b_{i,t} = z_{i,t} - \sqrt{\zeta \frac{w_t}{P_t}}$
- Quantity is a linear function of knowledge capital:

$$\mathbf{q}_t = \left\{ \underbrace{2\frac{\zeta}{L} J}_{\text{labor cost}} + \underbrace{\Sigma}_{\text{substitutability}} + \underbrace{K \circ \Sigma}_{\text{ownership weight} \times \text{substitutability}} \right\}^{-1} \mathbf{z}_t$$

  - J: matrix with all elements equal to 1
- Ownership-weighted gross profits are expressed in quadratic form: $\sum_j \kappa_{ij} \pi_{j,t} = \mathbf{z}_t^T Q^i \mathbf{z}_t$

LQ Differential Game

- Given other players' strategy $\{x_{j,t}\}_{j\neq i, t\geq 0}$, firm i chooses R&D effort $\{x_{i,t}\}_{t\geq 0}$ to maximize

$$\max_{\{x_{i,t}\}_{t\geq 0}} \quad V^i(\mathbf{z}_0) \equiv \mathbb{E}_0\left[\int_0^\infty \exp(-\rho t)\left\{\sum_j \kappa_{ij}\left(\pi_{j,t} - x_{j,t}^2\right)\right\} dt\right]$$

subject to $d\mathbf{z}_t = (\beta\Omega\mathbf{z}_t + \mu\mathbf{x}_t)\,dt + \gamma\mathbf{z}_t dW_t$

- Firm i's HJB equation:

$$\rho V^i(\mathbf{z}) = \max_{x_i}\left\{\mathbf{z}^T Q^i \mathbf{z} - \sum_j \kappa_{ij} x_j^2 + V_{\mathbf{z}}^i(\mathbf{z})\left[\Omega\mathbf{z} + \mu\mathbf{x}\right] + \frac{\gamma^2}{2}\mathbf{z}^T V_{\mathbf{zz}}^i(\mathbf{z})\mathbf{z}\right\}$$

HJB Equations $\Longrightarrow$ Riccati Equations

- Guess and verify $V^i(\mathbf{z}) = \mathbf{z}^T X^i \mathbf{z}$
- X^i is the solution of stacked algebraic Riccati equations Riccati
- All public patenting firms in the US in our dataset $\simeq$1000 firms $\Longrightarrow$
  - $1000^3 = 1$ billion undetermined coefficients

HJB Equations $\Longrightarrow$ Riccati Equations

- Guess and verify $V^i(\mathbf{z}) = \mathbf{z}^T X^i \mathbf{z}$
- X^i is the solution of stacked algebraic Riccati equations Riccati
- All public patenting firms in the US in our dataset $\simeq$1000 firms $\Longrightarrow$
  - $1000^3 = 1$ billion undetermined coefficients

Oligopolistic Schumpeterian growth model	Computation time (n firms)	Number of firms	Space of productivity
Cavenaile et al. (2023)	$O(2^n)$	4	6 grids
Our model	$O(n^4)$	Around 1000	Continuous

BGP Equilibrium

- R&D strategy: $x_{i,t} = \left(\mu X_i^i\right)^T \mathbf{z}_t$ where X_i^i is the i th column of X^i
- The law of motion is rewritten as $d\mathbf{z}_t = \Phi \mathbf{z}_t dt + \gamma \mathbf{z}_t dW_t$ where

$$\underbrace{\Phi}_{\text{technology transition matrix}} \equiv \underbrace{\beta\Omega}_{\text{spillover}} + \underbrace{\mu^2 \begin{bmatrix} X_1^1 & \cdots & X_n^n \end{bmatrix}^T}_{\text{R\&D}}$$

Theorem

Consider the deterministic economy ($\gamma = 0$). If the technology transition matrix Φ is irreducible,
(i) there exists a largest positive eigenvalue of Φ, g, and associated strictly positive eigenvector, $\mathbf{z}^*$
(ii) there exists a globally stable BGP such that the productivity growth rate of all firms is g and productivity distribution is a scalar multiple of $\mathbf{z}^*$

- Proof: Perron–Frobenius Theorem
- "Φ is irreducible" $\Longleftrightarrow$ "All firms are directly or indirectly connected technologically"

Aggregation: Output and Expected Utility

- Output is expressed in quadratic form: Equilibrium Summary

$$Y_t = \mathbf{q}_t^T \mathbf{b}_t - \frac{1}{2}\mathbf{q}_t^T \Sigma \mathbf{q}_t = \mathbf{z}_t^T Q \mathbf{z}_t$$

  - $\mathbf{a}_t$, $\mathbf{b}_t$, $\mathbf{z}_t$, and $\mathbf{q}_t$ grow at the same rate on BGP in deterministic economy ($\gamma = 0$).

- Expected utility is expressed in quadratic form: X

$$\mathbb{E}_t \left[\int_t^{\infty} \exp\left(-\rho s\right) C_s ds \middle| \mathbf{z}_t \right] = \mathbf{z}_t^T X \mathbf{z}_t$$

  - Solve the equilibrium once $\Longrightarrow$ Can compute expected utility for any $\mathbf{z}_t$

- Expected utility under social optimum is also expressed in quadratic form Social Optimum

Common Ownership Weight: Backus et al. (2021)

$$\kappa_{ij} \equiv \frac{\mathbf{s}_i^T \mathbf{s}_j}{\mathbf{s}_i^T \mathbf{s}_i} \text{ where } \mathbf{s}_i \text{ is firm } i\text{'s ownership structure}$$

Product Substitutability

$$\underbrace{\sigma_{ij}}_{\text{substitutabiliy}} = \alpha \underbrace{\sum_k \psi_{k,i}\psi_{k,j}}_{\text{product cosine similarity}} \quad (i \neq j)$$

- Hoberg and Phillips (2016) estimates product similarity using product descriptions in 10-K
- Pellegrino (2024) estimates α to align with the cross-price elasticity of demand

Technological Proximity: Bloom et al. (2013)

- T_i: the vector representing the share of patents held by firm i in each technology class
  - (i) subclass-level ($\approx$ 600) or (ii) group-level ($\approx$ 4000) classifications
- Jaffe (1986) measure:

$$\tilde{\omega}_{ij} = \frac{T_i T_j'}{\left(T_i T_i'\right)^{1/2} \left(T_j T_j'\right)^{1/2}}$$

  - Assumption: Spillovers exist only within the same technology classes
- Mahalanobis measure for robustness
  - Accounts for spillovers between technology classes
  - Based on frequency with which patents are taken out in different classes within firm

Technological Proximity: Bloom et al. (2013)

- Group-level patent classification, Jaffe measure, Stack for 5 years

Initial Distribution of Knowledge Capital

1. Profit $\pi_{i,t} \Longleftarrow$ "Revenue" $-$ "Costs of goods sold"
2. Quantity $\mathbf{q}_t \Longleftarrow \pi_{i,t}/P_t = \sum_j \kappa_{ij}\sigma_{ij}q_{i,t}q_{j,t}$
   - P_t is measured by GDP deflator
3. $\zeta/L \Longleftarrow$ match the total cost
4. Knowledge capital $\mathbf{z}_t \Longleftarrow \mathbf{q}_t = \left\{2\frac{\zeta}{L}J + \Sigma + K \circ \Sigma\right\}^{-1}\mathbf{z}_t$

Distributions of Estimated Knowledge Capital and Quantity

(a) Log of Quantity

(b) Log of Knowledge Capital

Estimation of the Law of Motion

$$z_{i,t+1} - z_{i,t} = \beta \sum_{j \neq i} \tilde{\omega}_{ij,t} z_{j,t} + \text{Year FE}_t + \varepsilon_{i,t}$$

	(1)	(2)	(3)
	$z_{i,t+1} - z_{i,t}$	$z_{i,t+1} - z_{i,t}$	$z_{i,t+1} - z_{i,t}$

- IV: User cost of R&D, driven by state-level tax variations (Wilson, 2009; Bloom et al., 2013)

Identification: Summary

- Publicly available data + Compustat

Notation	Description	Value	Source
$\Psi^T\Psi$	Product proximity		Form 10-K, Hoberg and Phillips (2016)
$\tilde{\Omega}$	Technological proximity		USPTO, Patent classification
K	Common ownership weights		Form 13F, Backus et al. (2021)
α	Product proximity $\rightarrow$ Substitutability	.12	Pellegrino (2024)
β	Technological proximity $\rightarrow$ Spillover	.00014	Estimate the law of motion
γ	St.d. of idiosyncratic shocks	.027	Estimate the law of motion
ζ/L	Labor augmentation efficiency	.0063	Compustat, Cost of goods sold
ρ	Discount rate	.10	
μ	R&D efficiency	.05	1.6% economic growth rate

Goodness of Fit b/w Model and Data

- Model (x-axis) vs Data (y-axis) : firm-level profits (targeted), sales and R&D expenditures

(a) Log of Profit (Targeted)

(b) Log of Sales

(c) Log of R&D Expenditure

Different Ownership Structure: R&D Expenditure and Growth Rate

(a) R&D Expenditure

(b) Expected Growth Rate

- Concentration in production: appropriability of return from innovation $\uparrow \Longrightarrow g \uparrow$
- Concentration in R&D: internalization of business stealing $>$ technology spillover $\Longrightarrow g \downarrow$

Different Ownership Structure: Output and Social Welfare

(a) Total Output

(b) Expected Social Welfare

- Ownership concentration in both R&D and production tends to reduce welfare

Trends of Growth Rates

Stochastic process of log Y_t

(a) Expected Economic Growth Rates

(b) Growth Due to R&D

(c) Growth Due to Tech Spillover

- Economic growth rate under common ownership deviates from that under dispersed ownership and approaches that under monopoly
- Dispersed ownership $\Longrightarrow$ Observed common ownership: $g \downarrow$ by 0.043% in 2017

Trends of Growth Rates (Only Ownership Structure of R&D Differs)

(a) Expected Economic Growth Rates

(b) Growth Due to R&D

(c) Growth Due to Tech Spillover

- Economic growth rate under common ownership deviates from that under dispersed ownership and approaches that under monopoly
- Dispersed ownership $\Longrightarrow$ Observed common ownership: $g \downarrow$ by 0.084% in 2017

Uniform R&D Subsidy

(a) Expected Growth

(b) Expected Social Welfare

- Optimal rate in 2017 is $s = 33\%$, which increases g by 0.25%
- CE welfare loss relative to optimal R&D allocation: 0.7% ($s = 0\%$) $\Longrightarrow$ 0.1% ($s = 30\%$)

Alternative Corporate Governance Models: Ederer and Pellegrino (2024)

1. Super-proportional influence: $\tilde{\kappa}_{ij} = \frac{\sum_{z=1}^{Z} s_{iz}\gamma_{iz}s_{jz}}{\sum_{z=1}^{Z} s_{iz}\gamma_{iz}s_{iz}}$ where $\gamma_{iz} = \sqrt{s_{iz}}$
2. Blockholder influence: $\tilde{\kappa}_{ij} = \frac{\sum_{z=1}^{Z} s_{iz}b_{iz}s_{jz}}{\sum_{z=1}^{Z} s_{iz}s_{jz}} \quad (i \neq j)$, where $b_{iz} = 1$ if $s_{iz} > 5\%$
3. Rational investor inattention
   - Gilje et al. (2020) (GGL) estimate the probability that an investor votes against Institutional Shareholders Service recommendations
   - Utilize the estimate to capture the investor's level of attention
4. Governance frictions and entrenchment
   - Azar and Ribeiro (2021) (AR) estimate an objective function where the manager of firm i discounts other firms' profit by τ_i

Alternative Corporate Governance Models

(a) Expected Growth

(b) Expected Social Welfare

Conclusion

- Quantitative endogenous growth model incorporating ownership structure and competition
  - Match to data at firm (pair) level
- Ownership concentration in production:
  - Appropriability of returns from innovation $\uparrow \Longrightarrow g \uparrow$
  - Dispersed ownership $\Longrightarrow$ Observed common ownership: $g \uparrow$ by 0.027% in 2017
- Ownership concentration in R&D:
  - Internalization of business stealing $\Longrightarrow g \downarrow$
  - Internalization of technology spillover $\Longrightarrow g \uparrow$
  - Dispersed ownership $\Longrightarrow$ Observed common ownership: $g \downarrow$ by 0.084% in 2017
- Uniform R&D subsidy
  - Optimal rate in 2017 is $s = 32\%$, which increases g by 0.25%
  - CE welfare loss relative to optimal R&D allocation: 0.7% ($s = 0\%$) $\Longrightarrow$ 0.1% ($s = 30\%$)

Generalized Hedonic-Linear Demand (Pellegrino, 2024)

- Quality:

$$b_i = (1-\alpha)\,\hat{b}_i + \alpha \sum_{k=n+1}^{n+n_k} \psi_k \hat{b}_k$$

- Inverse demand:

$$\frac{\mathbf{p}}{P} = \mathbf{b} - \Sigma \mathbf{q}$$

- Inverse cross price elasticity of demand:

$$\frac{\partial \log p_i}{\partial \log q_j} = -\frac{q_j}{p_i} \cdot \sigma_{ij}$$

- Cross price elasticity of demand:

$$\frac{\partial \log q_i}{\partial \log p_j} = -\frac{p_j}{q_i} (\Sigma^{-1})_{ij}$$

Back

Static Profits

- Real gross profit: $\frac{\pi_{i,t}}{P_t} = \sum_j \kappa_{ij}\sigma_{ij}q_{i,t}q_{j,t}$
- Labor market clearing: $L = \sum_i \frac{q_{i,t}}{a_{i,t}} \Longrightarrow \sqrt{\zeta \frac{w_t}{P_t}} = \frac{\zeta}{L}\sum_i q_{i,t}$
- $\mathbf{q}_t = N\mathbf{z}_t$ where $N \equiv \left\{2\frac{\zeta}{L}J + \Sigma + K \circ \Sigma\right\}^{-1}$
- N_i: the i th row of N
- Ownership weighted profit:

$$\sum_j \kappa_{ij}\frac{\pi_{j,t}}{P_t} = \sum_j \kappa_{ij}\sum_h \kappa_{jh}\sigma_{jh}q_{j,t}q_{h,t} = \mathbf{z}_t^T Q^i \mathbf{z}_t$$

where

$$Q^i = \frac{1}{2}\sum_j \kappa_{ij}\sum_h \kappa_{jh}\sigma_{jh}\left(N_j^T N_h + N_h^T N_j\right)$$

Riccati Equations

- $V^i(\mathbf{z}) = \mathbf{z}^T X^i \mathbf{z}$ where X^i is the solution of the stacked Riccati equation

$$0 = Q^i - \mu^2 \sum_j \kappa_{ij} X_j^j \left(X_j^j\right)^T + \left(\Phi - \frac{1}{2}\left(\rho - \gamma^2\right) I\right)^T X^i + X^i \left(\Phi - \frac{1}{2}\left(\rho - \gamma^2\right) I\right)$$

  - $X_i^i \equiv$ the i th column of X^i
  - $\Phi \equiv \Omega + \mu^2 \begin{bmatrix} X_1^1 & \cdots & X_n^n \end{bmatrix}^T$
- Algorithm: Given $\begin{bmatrix} X_\tau^1 & \cdots & X_\tau^n \end{bmatrix}$, update $\begin{bmatrix} X_{\tau-\Delta}^1 & \cdots & X_{\tau-\Delta}^n \end{bmatrix}$ by

$$-\frac{X_\tau^i - X_{\tau-\Delta}^i}{\Delta} = Q^i - \mu^2 \sum_j \kappa_{ij} X_{j,\tau}^j \left(X_{j,\tau}^j\right)^T + \left(\Phi_\tau - \frac{1}{2}\left(\rho - \gamma^2\right) I\right)^T X_\tau^i + X_\tau^i \left(\Phi_\tau - \frac{1}{2}\left(\rho - \gamma^2\right) I\right)$$

Back

Summary of Equilibrium

Description	Expression
Production strategy	$\mathbf{q}_t = N\mathbf{z}_t$
R&D strategy	$\mathbf{x}_t = \mu \tilde{X} \mathbf{z}_t$
Law of motion	$d\mathbf{z}_t = (\Omega \mathbf{z}_t + \mu \mathbf{x}_t)\, dt + \gamma \mathbf{z}_t dW_t$
Profit of final producers	$\Pi_t^F / P_t = \mathbf{q}_t^T \left(\frac{1}{2}\Sigma\right) \mathbf{q}_t$
Total operating profit of firms	$\Pi_t / P_t = \mathbf{q}_t^T \left(\frac{1}{2}\Sigma \circ \left(K + K^T\right)\right) \mathbf{q}_t$
Labor income	$w_t L / P_t = \mathbf{q}_t^T \left(\frac{\zeta}{L} J\right) \mathbf{q}_t$
Output	$Y_t = \mathbf{q}_t^T \left(\frac{\zeta}{L} J + \frac{1}{2}\Sigma + \frac{1}{2}\Sigma \circ \left(K + K^T\right)\right) \mathbf{q}_t$
Consumption	$C_t = Y_t - \mathbf{x}_t^T \mathbf{x}_t$

Back

Output and Expected Utility

- Output: $Y_t = \mathbf{q}_t^T Q \mathbf{q}_t$ where

$$Q = \frac{\zeta}{L} J + \frac{1}{2}\Sigma + \frac{1}{2}\Sigma \circ \left(K + K^T\right)$$

- Expected utility:

$$V(\mathbf{z}_t) \equiv \mathbb{E}_t \left[\int_t^{\infty} \exp(-\rho s) C_s ds \middle| \mathbf{z}_t \right] = \mathbf{z}_t^T X \mathbf{z}_t$$

where X is the solution of the Lyapunov equation (obtained from households' HJB equation):

$$0 = Q - \mu^2 \tilde{X}^T \tilde{X} + X \left(\Phi - \frac{1}{2}\left(\rho - \gamma^2\right) I \right) + \left(\Phi - \frac{1}{2}\left(\rho - \gamma^2\right) I \right)^T X$$

Back

Social Optimum

- Static optimal allocation: $\mathbf{q}_t^* = N^* \mathbf{z}_t$ where $N^* \equiv \left\{ 2\frac{\zeta}{L} J + \Sigma \right\}^{-1}$
- Optimal output: $Y_t^* = \mathbf{z}_t^T Q^* \mathbf{z}_t$ where $Q^* = \frac{1}{2} N^*$
- Optimal expected utility:

$$V^*(\mathbf{z}_t) \equiv \mathbb{E}_t \left[\int_t^\infty \exp(-\rho s) C_s ds \middle| \mathbf{z}_t \right] = \mathbf{z}_t^T X^* \mathbf{z}_t,$$

where X^* is the solution of the Riccati equation (obtained from planner's HJB equation):

$$0 = Q^* - \mu^2 (X^*)^2 + X^* \left(\Phi^* - \frac{1}{2} (\rho - \gamma^2) I \right) + \left(\Phi^* - \frac{1}{2} (\rho - \gamma^2) I \right) X^*$$

- Optimal R&D: $\mathbf{x}_t^* = \mu X^* \mathbf{z}_t$
- Optimal technology transition matrix: $\Phi^* = \Omega + \mu^2 X^*$

Back

Stochastic Process of Output

- Applying Itô's lemma,

$$d\log Y_t = \left[\frac{\mathbf{z}_t^T\left(Q\Phi + \Phi^T Q\right)\mathbf{z}_t}{Y_t} + \gamma^2\left\{\frac{\sum_i z_{i,t}^2 Q_{ii}}{Y_t} - \frac{2\mathbf{z}_t^T Q\,\mathrm{diag}\left(\mathbf{z}_t^2\right)Q\mathbf{z}_t}{Y_t^2}\right\}\right]dt + \frac{2\gamma\mathbf{z}_t^T Q\,\mathrm{diag}\left(\mathbf{z}_t\right)}{Y_t}dW_t$$

where $Y_t = \mathbf{z}_t^T Q\mathbf{z}_t$ and $\Phi = \Omega + \mu^2\tilde{X}$

Description	Expression
Tech Spillover	$\mathbf{z}_t^T\left(Q\Omega + \Omega Q\right)\mathbf{z}_t / Y_t$
R&D	$\mu^2\mathbf{z}_t^T\left(Q\tilde{X} + \tilde{X}^T Q\right)\mathbf{z}_t / Y_t$
Ito	$\gamma^2\left\{\sum_i z_{i,t}^2 Q_{ii}/Y_t - 2\mathbf{z}_t^T Q\mathrm{diag}\left(\mathbf{z}_t^2\right)Q\mathbf{z}_t/Y_t^2\right\}$
Total	$\mathbb{E}\left[d\log Y_t\right]$
